Purpose

This technical memo documents the TxBLEND hydrodynamic and salinity transport simulations conducted for the Guadalupe Estuary at the request of the Guadalupe-San Antonio Bay and Basin Expert Science Team (G-SA BBEST) to aid their effort in fulfilling the mandates of the Senate Bill 3 process for developing environmental flow recommendations for the Guadalupe and Mission-Aransas estuaries. This document focuses on the validation of salinity at sites in the upper Guadalupe Estuary. Additional information about model calibration and performance can be found in the July 2010 report, *TxBLEND Model Calibration and Validation for the Guadalupe and Mission-Aransas Estuaries* (TWDB 2010a), which was presented to a G-SA BBEST Estuary Subcommittee in May 2010.

Background

TWDB staff recently completed a calibration and validation exercise for the Guadalupe and Mission-Aransas estuaries TxBLEND hydrodynamic and salinity transport model (TWDB 2010a). Since that time, new information has become available allowing staff to update and extend the hydrology for the Guadalupe Estuary to include data for gaged and ungaged inflows, diversions, and returns through 2009. Additionally, HDR Engineering, Inc. provided to TWDB their compilation of diversion and return flow data for the Guadalupe and San Antonio River basins for the period 1941-2009. This diversion and return flow data differs from the official record maintained by the TWDB (which includes data obtained from the Texas Commission on Environmental Quality and the South Texas Water Master), but is based on data obtained directly from the permitted diverters and dischargers within the basin (see TWDB 2010b for additional explanation). Therefore, considering the HDR diversion and return flow data to be more complete, the G-SA BBEST requested that TWDB develop an updated hydrology, based on the HDR data, and use this as an input to the TxBLEND model to obtain salinity simulations for use in conducting GIS analyses as part of the effort to determine freshwater inflow recommendations for the estuary. Additionally, the G-SA BBEST requested that TWDB conduct additional validation for sites of interest in

the upper Guadalupe Estuary and in the middle of San Antonio Bay. This technical memo documents the differences in model inputs between the previously reported TxBLEND simulations (*as documented in* TWDB 2010a) and the current simulations being provided to the G-SA BBEST for analysis, as well as the model results and validation of salinity at selected locations within the Guadalupe Estuary.

Model Grid

The full TxBLEND model grid for the Guadalupe and Mission-Aransas estuarine system is presented in TWDB 2010a; however, a close-in view of the Guadalupe Estuary model grid is show in Figure 1. Within the Guadalupe Estuary, the G-SA BBEST selected ten locations of interest (G1-G10; Figure 2) which correspond to specific TxBLEND nodes within the model grid (Table 1). TWDB conducted additional salinity validation for these locations of interest. Model validation comparisons were made for G1, G2, G3, G4, DELT (near G3), SANT, MOSQ (near G6), and GBRA1 (near G10).

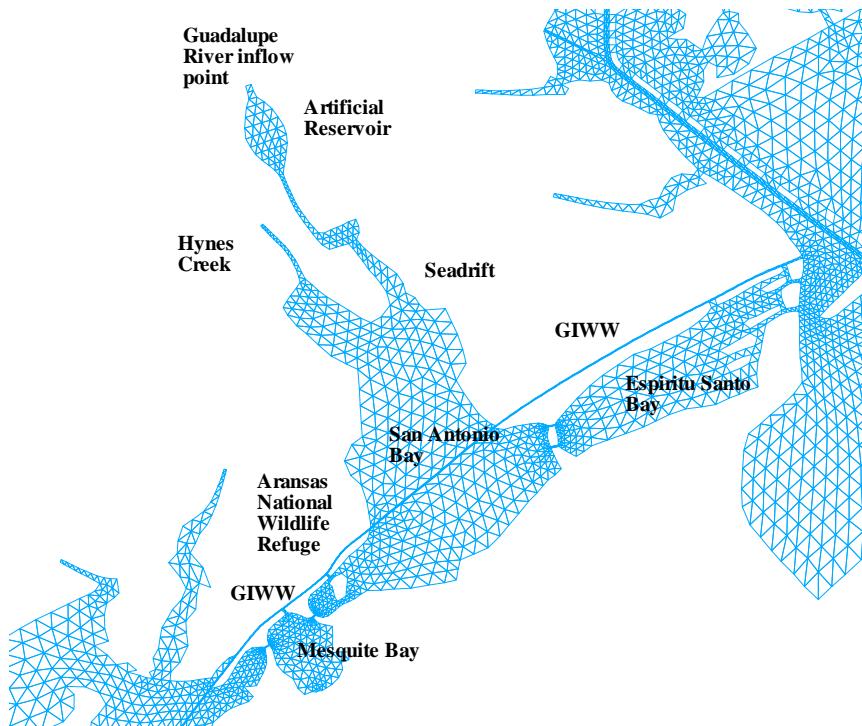

Figure 1. Close-up of the Guadalupe and Mission-Aransas TxBLEND computational grid focusing on the Guadalupe Estuary. The full model grid includes Matagorda, Aransas, Copano, and Corpus Christi bays (see TWDB 2010a).

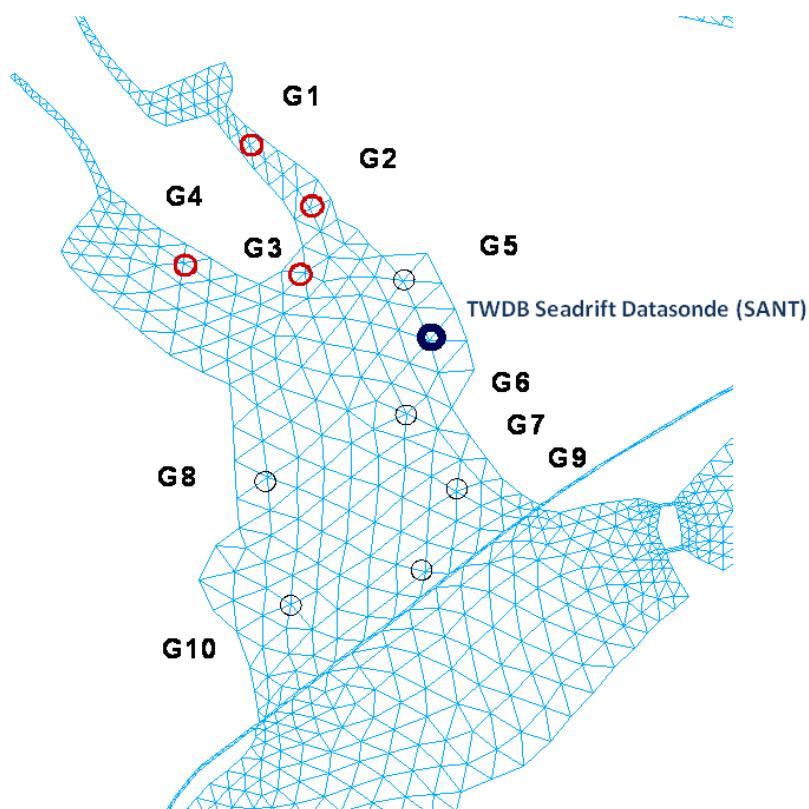

Figure 2. Ten sites (G1 - G10) selected by the G-SA BBEST in San Antonio Bay. Also shown is the TWDB Datasonde station (SANT), near Seadrift. Model validation comparisons were made for G1, G2, G3, G4, DELT (near G3), SANT, MOSQ (near G6), and GBRA1 (near G10).

Table 1. Selected site of interest and corresponding nodes within the TxBLEND model grid.

Site	Description	TxBLEND Grid Node
G1	upper estuary	2773
G2	upper estuary	2612
G3	upper estuary near DELT datasonde station	2570
G4	Hyne's Bay	2687
G5	upper estuary near SANT datasonde station	2347
G6	middle estuary near MOSQ datasonde station	2175
G7	middle estuary	2058
G8	middle estuary	2461
G9	middle estuary	2113
G10	middle estuary near GBRA1 datasonde station	2393

Hydrology

The previous calibration and validation of the Guadalupe-Mission-Aransas TxBLEND model (TWDB 2010a) relied on hydrology version #TWDB201002, which was not fully updated for diversion and return flows through 2009. Additionally, calibration and validation was based on a modified version of the #TWDB201002 hydrology, whereby inflows from four ungauged coastal watersheds surrounding San Antonio Bay (WS24607, WS24608, WS24603, and WS24606; see Figure 5 in TWDB 2010b and Appendix A, Figure A-1) were not included. These watersheds were excluded, because the model has a singular inflow point, the Guadalupe River inflow point. By including the contribution of these watersheds in the Guadalupe River inflow point, model salinity values were too low compared to observed salinity data at the SANT datasonde station near Seadrift (see Figure 2 for SANT location).

Recently, TWDB obtained an independent compilation (prepared by HDR Engineering, Inc.) of diversions and return flows in the Guadalupe and San Antonio river basins below USGS stream gages #8177500 (Coleto Creek near Victoria), #8176500 (Guadalupe River at Victoria), and #81888500 (San Antonio River at Goliad). At the request of the G-SA BBEST, this data was used to develop an alternative hydrology of inflows entering the Guadalupe Estuary (version #HDR201001). Details of this alternative hydrology are reported in the technical memo *Coastal Hydrology for the Guadalupe Estuary: Updated Hydrology with Emphasis on Diversion and Return Flow Data for 2000-2009, November 2010* (TWDB 2010b). For the simulations of TxBLEND considered in this memo, version #HDR201001, including all ungauged watersheds, was used as an input to the model. Figure 3 shows the difference in combined inflows for the modified version #TWDB201002 (Guad2009JM) used in the TxBLEND calibration and validation as compared to the alternative hydrology #HDR201001 used for this technical memo. The largest difference occurs during the 2009 drought, with the newer hydrology showing lower inflows to the estuary. Appendix A also explores in more detail the differences between the two hydrology estimates.

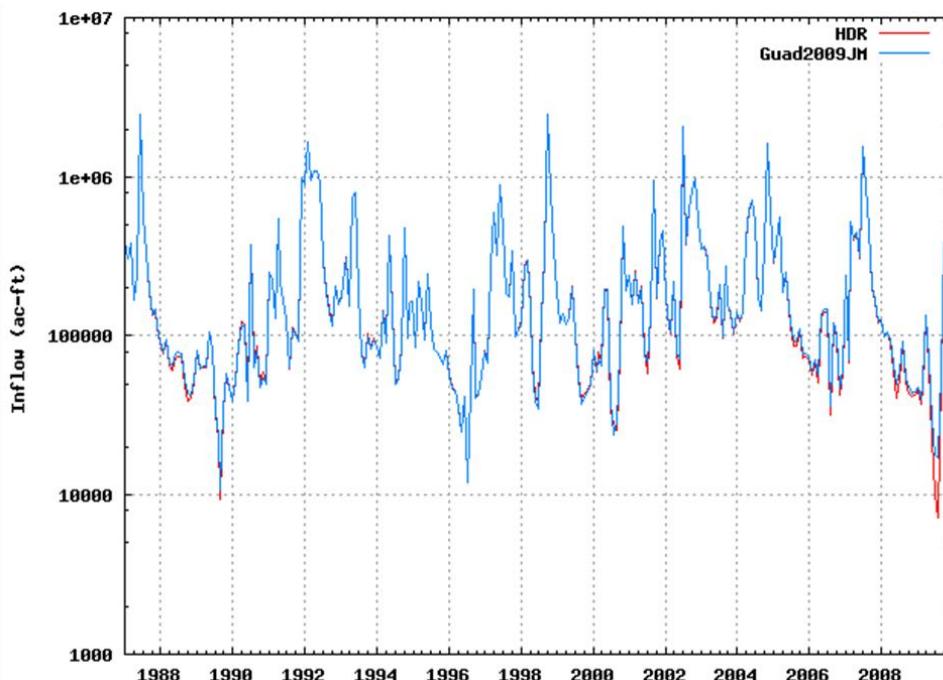

Figure 3. A comparison of estimates of combined inflows to the Guadalupe Estuary for the modified hydrology version #TWDB201002 (Guad2009JM, blue) and the alternative hydrology version #HDR201001 (red); ordinate is a log scale.

Salinity Data

TxBLEND model calibration and validation require salinity data. While time-series salinity data is preferred due to increased reliability for model comparisons, it is not often available at more than a few select locations within the estuary (Figure 4). Alternatively, numerous point-measurement data are available from monitoring programs conducted by the Texas Parks & Wildlife Department Coastal Fisheries Program, the Texas Commission on Environmental Quality, and the Texas Department of State Health Services. Therefore, though point measurement data are available to serve as a guide for comparison, as with time-series data, relatively little data is available in the upper estuary. Figure 5 shows point measurement data extracted within an area adjacent to sites G1 – G4.

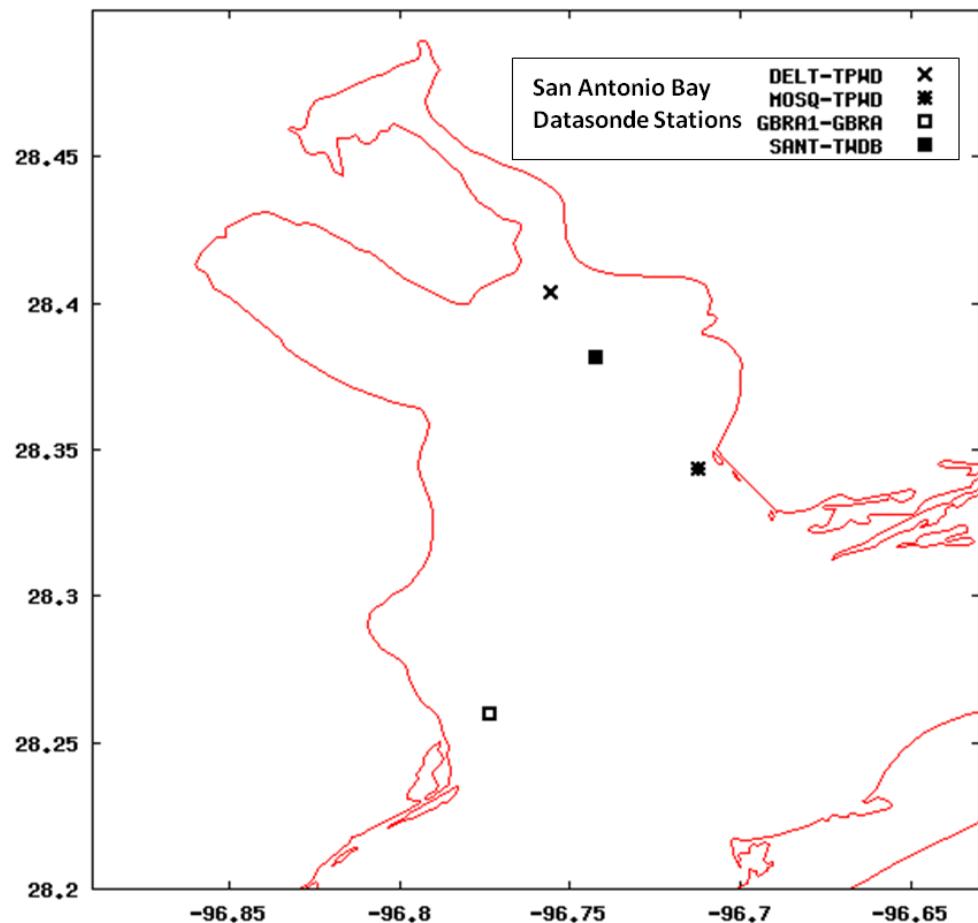

Figure 4. Datasonde station locations in San Antonio Bay which provide time-series salinity data. DELT (x), MOSQ (*), and SANT (■) stations are maintained by TPWD, though SANT is funded by the TWDB as part of the co-operative Datasonde Program. GBRA1 (□) is funded by the Guadalupe-Blanco River Authority and maintained by the Conrad Blucher Institute.

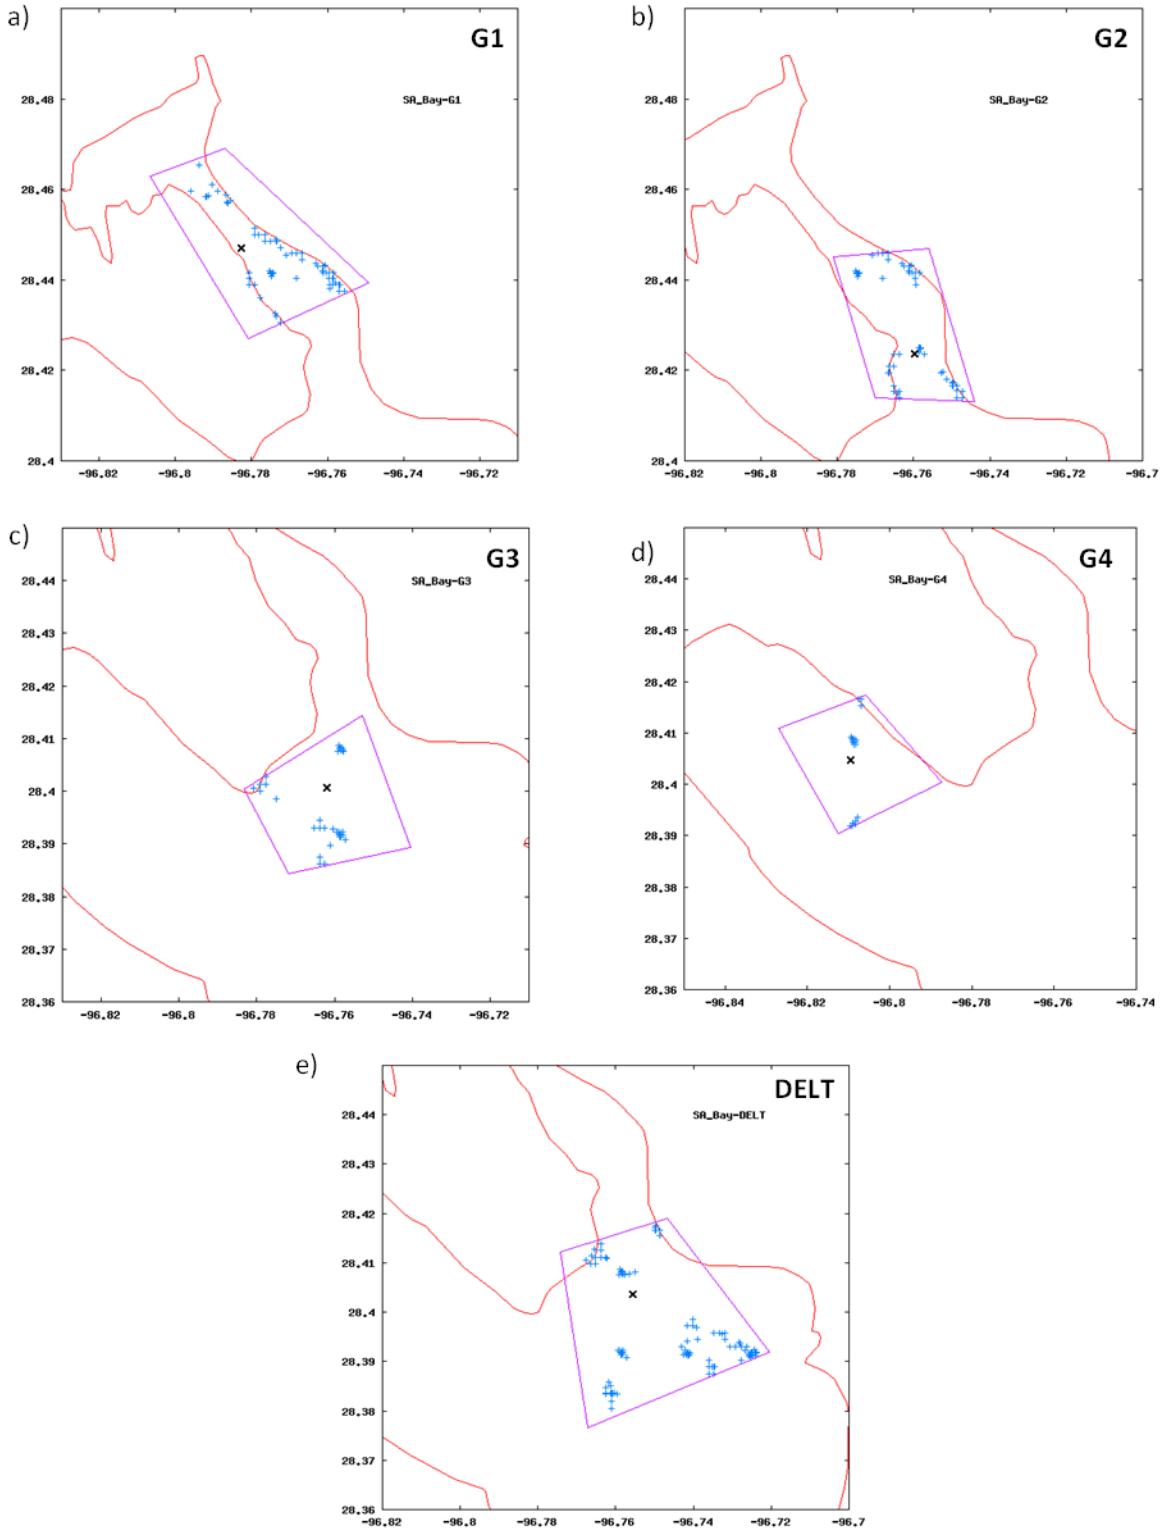

Figure 5. Sites of interest in the upper Guadalupe Estuary, (a) G1, (b) G2, (c) G3, (d) G4, (e) DELT. Each site (marked by x-symbol) is bounded by a polygon which defines the adjacent area from which point-measurement data (blue + symbols) were extracted for use in model validation. G1-G4 were locations of interest selected by the G-SA BBEST; DELT is a TPWD datasonde station in the upper estuary.

Table 2. Latitude and Longitude of the corners defining polygons surrounding sites G1 – G4 and DELT, from which point measurement salinity data was extracted for model validation.

Results

Comparison to Observed Salinity Data

Figures 6 to 13 show that the TxBLEND model captures major salinity trends in the system reasonably, but higher frequency fluctuations are more difficult to simulate. The model also performs better at mid and lower bay locations than in the upper estuary. Summary statistics, comparing simulated to observed salinities, are shown in Table 3.

It is important to remember that relatively little to no data is available for model calibration in the upper estuary. Moreover, the upper estuary simulations of salinity are affected by the river boundary condition, which is set in relatively close proximity to the bay, and by the large size of the grid cells in this area. Improvements in model simulations of upper estuarine salinity conditions would require modifications to the TxBLEND model to move the river boundary further inland and reduce the size of the grid cells. While it is possible to make such modifications, these are not feasible in the time available to the BBEST. TxBLEND models of the major bays were not originally set up to focus on upper estuarine salinity dynamics and so less attention has been given to improving model performance in these bay locations. With increasing interest in modeling salinity in the upper estuarine zone and with increased access to data for these areas, TWDB can work to improve TxBLEND model performance in upper estuarine zones.

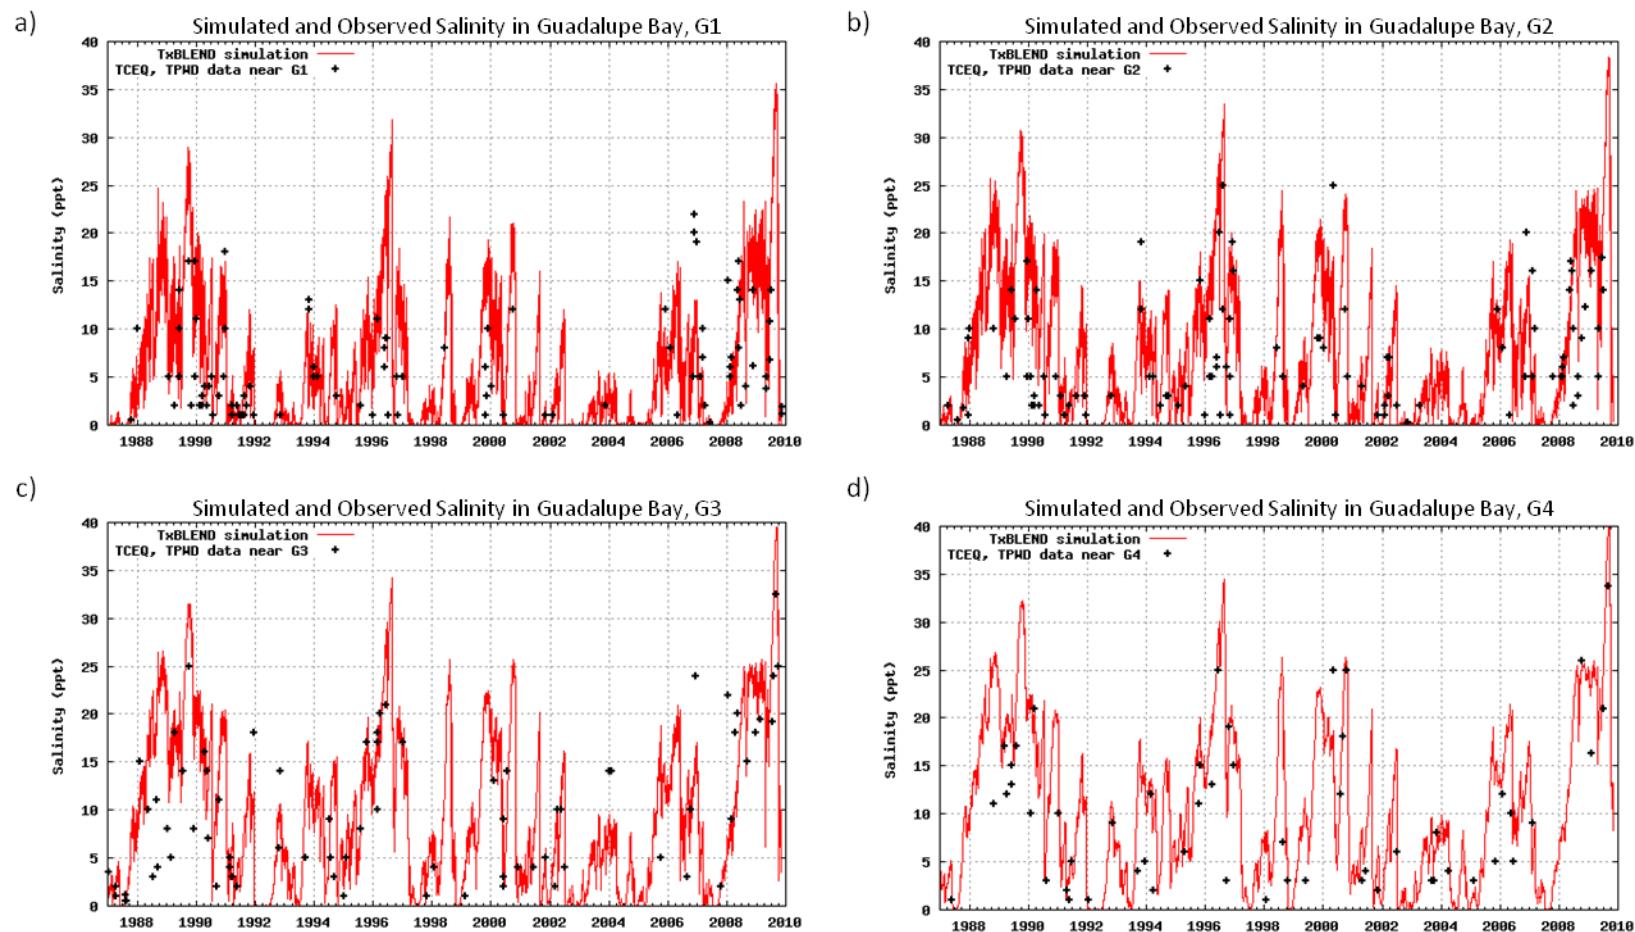

Figure 6. Simulated salinities (red) and observed point-measurement data (+ symbols) at sites (a) G1, (b) G2, (c) G3, and (d) G4 in the upper Guadalupe Estuary for the period 1987-2009.

Appendix A: Comparisons of Different Estimates of Hydrology for the Guadalupe Estuary

As reported in this technical memo, the recent calibration and validation of the Guadalupe-Mission-Aransas TxBLEND model (TWDB 2010a) was based on a modified version of hydrology #TWDB201002 referred to as version Guad2009JM, whereby four watersheds (WS24607, WS24608, WS24603, and WS24606) were excluded in the calculation of ungaged flows used as inputs to the Guadalupe River inflow point in the model (see Table A-1 and Figure A-1). Because the TxBLEND validation and simulations presented in this technical memo are based on an alternative hydrology (#HDR201001) which include the four, previously excluded watersheds (version HDR), it is important to compare the effect of this variation on estimates of total combined inflows to the estuary.

Table A-1. Three estimates of combined inflows for the period 1987-2009 which were compiled as input for TxBLEND. Guad2009 and Guad2009JM are based on hydrology version #TWDB201002, where Guad2009JM was used in the calibration and validation of TxBLEND presented in *TxBLEND Model Calibration and Validation for the Guadalupe and Mission-Aransas Estuaries* (TWDB 2010a). HDR is based on the alternative hydrology version #HDR201001 and was used in simulations conducted for the Guadalupe-San Antonio Bay & Basin Expert Science Team and as the basis for results presented in this technical memo.

	Hydrology Version #TWDB201002	Hydrology Version #HDR201001
Includes all ungaged watersheds	Guad2009 (F2)	HDR (F1)
Exclude watersheds WS24607, WS24608, WS24603, and WS24606	Guad2009JM (F3)	n/a

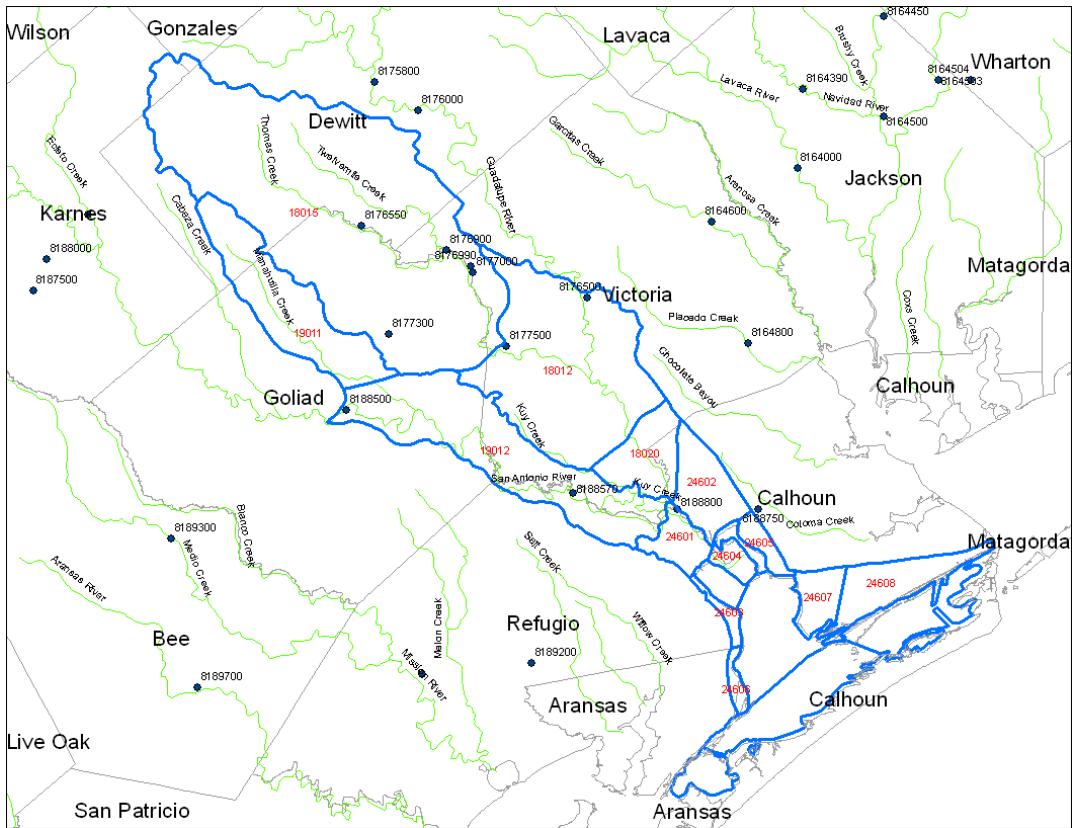

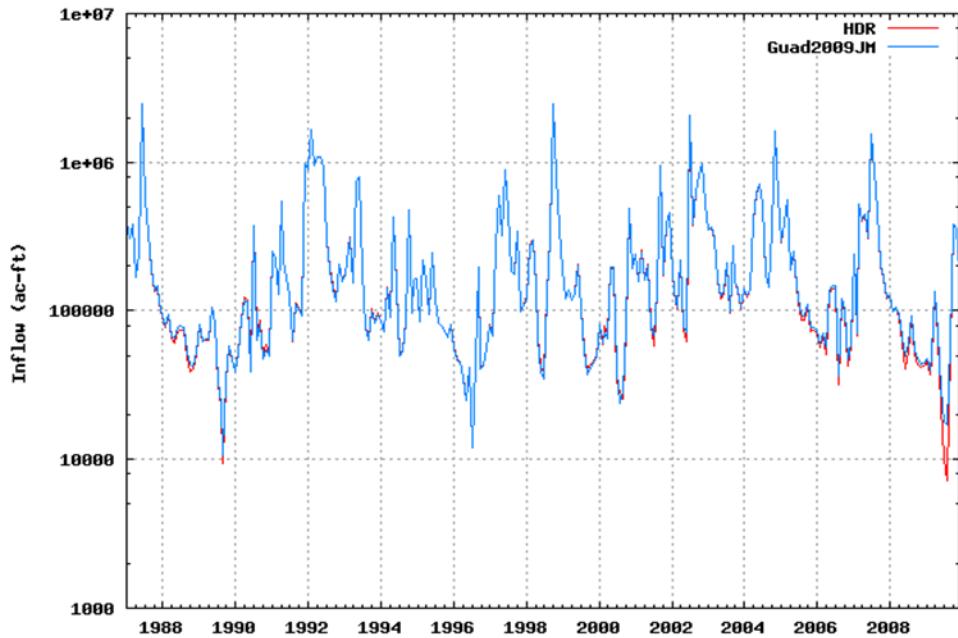

Figure A-1. Watershed delineation in the Guadalupe and San Antonio River basins. Ungaged watersheds, WS24607, WS24608, WS24603, and WS24606, were excluded in earlier estimates of combined inflows (Version #TWDB201002) used as inputs to the Guadalupe River inflow point in the TxBLEND model (as reported in TWDB 2010a). However, hydrology estimates used in this technical memo (Version #HDR201001) included the four ungauged watersheds.

Comparison of Versions of Hydrology

Figure 3 (earlier in the memo and again in Figure A-2) shows the comparison of estimates of combined inflows to the Guadalupe Estuary for the modified hydrology version #TWDB201002 (Guad2009JM) and the alternative hydrology version #HDR201001. Shown here as well, is a comparison of the most recent official hydrology developed by the TWDB (#TWDB201004) to the alternative hydrology (#HDR201001). Although a separate technical memo explains the development of coastal hydrology estimates in greater detail (TWDB 2010b), a comparison plot is shown here for informational purposes.

b)

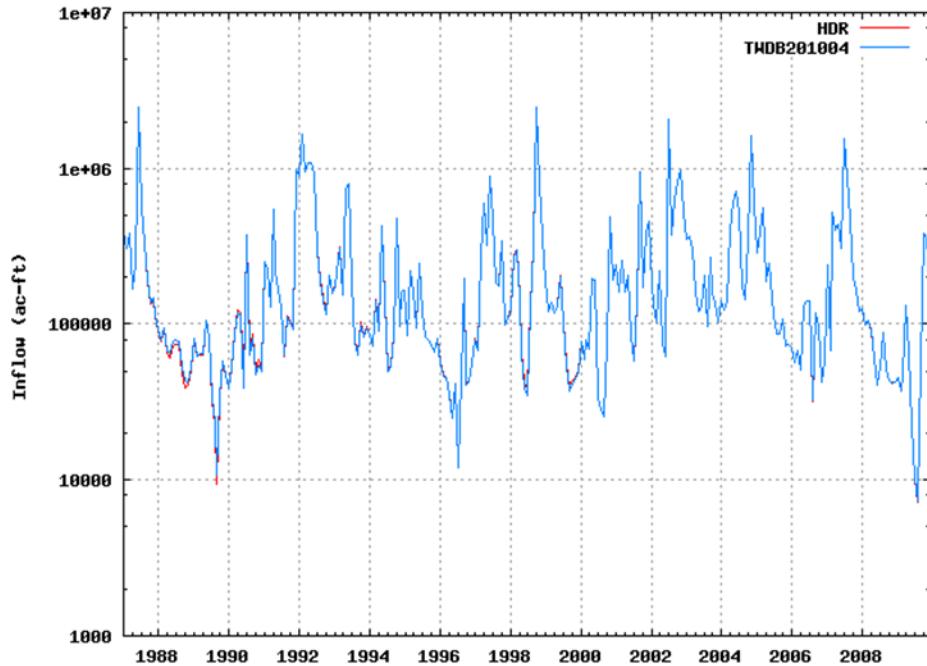

Figure A-2. (a) Same as Figure 3, a comparison of estimates of combined inflows to the Guadalupe Estuary for the modified hydrology version #TWDB201002 (Guad2009JM, blue; used to calibrate TxBLEND) and the alternative hydrology version #HDR201001 (red; used to generate salinity simulations for the Guadalupe-San Antonio BBEST as shown in this technical memo) and (b) a comparison of estimates for the most recent TWDB hydrology #TWDB201004 (blue) and the alternative hydrology version #HDR201001 (red); ordinate is a log scale.

The summer months of 2009 were a very dry period with river inflows greatly reduced as compared to other wetter years. During such conditions, it is interesting to evaluate the contribution of the four ungaged coastal watersheds, immediately adjacent to San Antonio Bay but located south of the mouth of the Guadalupe River, on total inflows to the estuary. Table A-2 shows the estimated combined inflows as calculated according to the above diagram. In most months, the four subwatersheds provide at least small contribution of inflows (greater than a 1,000 to several thousand acre-feet, as shown in Column F2-F3), with wetter months having an larger contribution and dry months, a lesser contribution down to a few hundred acre-feet or less.

The differences shown in Column F3-F1 however, are caused not only by the difference in the four watersheds but also by the recent updates to the hydrology (version #HDR201001) where net diversions, such as in 2009, reduced estimated inflows to the estuary (Column F1) – in comparison to the older version #TWDB201002 of hydrology (Column F2).

Table A-2. Three estimates of combined inflows used as input to the Guadalupe River inflow point in TxBLEND inflows and their differences (ac-ft). Column F1 shows the alternative hydrology version #HDR201001 (HDR). Columns F2 and F3 show two estimates of TWDB hydrology based on version #TWDB201002, where Guad2009 (F2) includes all watersheds and Guad2009JM (F3) excludes four ungaged watersheds (WS24607, WS24608, WS24603, and WS24606). Column F3-F1 shows the difference between the TWDB201002 hydrology with four ungaged watersheds removed (used as the input for the initial calibration and validation of TxBLEND, as presented in TWDB2010a) and the HDR201001 hydrology (used as input for TxBLEND simulations for the Guadalupe-San Antonio Bay & Basin Expert Science Team). Column F2-F3 shows the effect of excluding the four ungaged watersheds for the TWDB201002 estimate of hydrology. Column F2-F1 shows the difference between the TWDB201002 inflows and HDR201001 inflows (used as input for TxBLEND simulations for the Guadalupe-San Antonio Bay & Basin Expert Science Team).
